Abstract

This interim report details the 4-month progress on a project to design, implement, and verify, a multi-core FPGA RISC processor. The project has been split into two stages: firstly to build a functional single-core RISC processor, and then secondly to add multiprocessor principles and functionality to it.

Current multiprocessor and network-on-chip communication methods have been discussed and how they could be included in this multi-core RISC design. To-date, a 16-bit instruction set architecture has been designed featuring common load/store instructions, comparison, and bitwise operations. A single-core processor has been implemented in Verilog and verified using simulations/test benches running various simple software programs.

Future tasks have been planned and will focus on the second stage of the project. Work will start on designing a loosely coupled multiprocessor communication interface and bringing them to the single-core processor.

Declaration of Academic Integrity

The candidate confirms that the work submitted is his/her own, except where work which has formed part of jointly-authored publications has been included. The contribution of the candidate and the other authors to this work has been explicitly indicated in the report. The candidate confirms that appropriate credit has been given within the report where reference has been made to the work of others.

This copy has been supplied on the understanding that no quotation from the report may be published without proper acknowledgement. The candidate, however, confirms his/her consent to the University of Leeds copying and distributing all or part of this work in any forms and using third parties, who might be outside the University, to monitor breaches of regulations, to verify whether this work contains plagiarised material, and for quality assurance purposes.

The candidate confirms that the details of any mitigating circumstances have been submitted to the Student Support Office at the School of Electronic and Electrical Engineering, at the University of Leeds.

Name: Ben David Lancaster

Chapter 1

Introduction

1.1 Why Multi-core?	11
1.2 Why RISC?	12
1.3 Why FPGA?	12

This project will detail the design, implementation, and verification, of a new multi-core RISC processor aimed at FPGA devices. This project was chosen due to my interest in processor design, in which I have only previously designed single-core RISC processors, and wish to extend this knowledge to gain a basic understanding of multi-core communication, design considerations, and the challenges of software and hardware parallelism first hand.

I will use this opportunity to further develop my knowledge of FPGA and processor design by implementing, designing, and verifying, a multi-core RISC processor from scratch, including the design of a communication interface between multiple cores.

1.1 Why Multi-core?

Moore's Law states that the number of transistors in a chip will double every 2 years. CPU designers would utilize the additional transistors to add more pipeline stages in the processor to reduce the propagation delay which would allow for higher clock frequencies.

The size of transistors have been decreasing and today can be manufactured in sub-10 nanometer range. However, the extremely small transistor size increases electrical leakage and other negative effects resulting in unreliability and potential damage to the transistor. The high transistor count produces large amounts of heat and requires increasing power to supply the chip. These trade-offs are currently managed by reducing the input voltage, utilising complex cooling techniques, and reducing clock frequency. These factors limit the performance of the chip significantly. These are contributing factors to Moore's Law *slowing* down. The capacity limit of the current-generation planar transistors is approaching and so in order for performance increases to continue, other approaches such as alternate transistor technologies like Multigate transistors [5], software and hardware optimisations, and multi-processor architectures are employed.

This report will focus on the latter: to produce a small multi-core processor that can utilise software-based parallelism to gain performance benefits, compared to a larger single-core

design.

1.2 Why RISC?

RISC architectures feature simpler and fewer instructions compared to CISC, which emphasises instructions that perform larger tasks. A single CISC instruction might be performed with multiple RISC instructions. Because of the fewer and simpler instructions, RISC machines rely heavily on software optimisations for performance. RISC instruction sets are based on load/store architectures, where most instructions are either register-to-register or memory reading and writing [6]. This constraint greatly reduces complexity.

RISC architectures are easier to design implement, especially for beginners, due to their simpler instructions that share the same pipeline, compared to CISC where there may be different pipeline for each instruction, which would greatly consume FPGA resources.

1.3 Why FPGA?

Field programmable gate arrays (FPGA) are a great choice for prototyping digital logic designs due to their programmable nature and quick development times.

My previous experience with FPGAs in previous projects will reduce risk and learning times and allow for more time to be spent on adding and extending features (discusses further in section 3).

FPGAs, however, may not be suitable for prototyping all register-transistor logic (RTL) projects. Larger RTL projects, such as large commercial processors, may greatly exceed the logic cell resources available in today's high-end FPGA devices and may only be prototyped through silicon fabrication, which can be expensive. This resource limitation will not be problem as the project aims to produce a small and minimal design specifically for learning about multi-core architectures.

Chapter 2

Background

2.1 Amdahl's Law and Parallelism	13
2.2 Loosely and Tightly Coupled Processors	13
2.3 Network-on-chip Architectures	14

2.1 Amdahl's Law and Parallelism

In many applications, not restricted to software, there may exist many opportunities for processes or algorithms to be performed in parallel. These algorithms can be split into two parts: a serial part that cannot be parallelised, and a part that can be parallelised. Amdahl's Law defines a formula for calculating the maximum *speedup* of a process with potential parallelism opportunities when ran in parallel with n many processors. Speedup is a term used to describe the potential performance improvements of an algorithm using an enhanced resource (in this case, adding parallel processors) compared to the original algorithm. Amdahl's Law is defined below, where the potential speedup S_p is dependant on the portion of program that can be parallelised p and the number of processing cores n :

$$S_p = \frac{1}{(1 - p) + \frac{p}{n}} \quad (2.1)$$

This formula will be used throughout the project to gauge the performance of the multi-core design running various software algorithms.

2.2 Loosely and Tightly Coupled Processors

Multiprocessor systems can be generalised into two architectures: loosely and tightly coupled, and each architecture has advantages and disadvantages. In loosely coupled systems, each processing node is self-contained – each node has its own dedicated memory and IO modules. Communication between nodes is performed over a *Message Transfer System (MTS)* [1] in a master-slave control architecture.

Scalability in loosely coupled systems is generally easier to implement as each node can simply be appended to the shared MTS interface without large modifications to the rest of

the system. Scalability is an important concern in this project as I wish to test the developed solution with a range of processing nodes.

As loosely coupled system's nodes feature their own memory and IO modules, they generally perform better in cases where interaction between nodes is not prominent – each node can store a separate part of the software program in its memory module allowing simultaneous executing of the program.

In scenarios where inter-node communication is prominent however, access to the MTS interface must be scheduled to avoid access conflicts which introduces delays and idle times in the software programs execution, resulting in lower throughput. Figure 2.1 shows a general layout of a loosely coupled multiprocessor system.

Tightly coupled systems feature processing nodes that do not have their own dedicated memory or IO modules – each node is directly connected to a shared memory module using a dedicated port. In scenarios where inter-node communication is prominent, tightly coupled systems are generally better suited as nodes are directly connected to a shared memory and do not need to wait to use a shared bus.

Figure 2.1: A loosely coupled multiprocessor system. Each node features its own memory and IO modules and uses a Message Transfer System to perform inter-node communication. Image source: [1].

Figure 2.2: A tightly coupled multiprocessor system. Nodes are directly connected to memory and IO modules. Image source: [1].

This project will utilise a loosely coupled architecture due to its easier scalability implementation and my previous experience with the design of single-core processors. Although it will require a scheduler to access the MTS, the experience and knowledge gained from this task will be greatly beneficial for future projects.

2.3 Network-on-chip Architectures

Network-on-chip (NoC) architectures implement on-chip communication mechanisms that are based on network communication principles, such as routing, switching, and massive scalability [7]. NoC's can generally support hundreds to millions of processing cores. Figure 2.3 shows an example 16-core network-on-chip architecture. NoC's can scale to very large sizes while not sacrificing performance because each processor core is able to drive the network rather than needing to wait for a shared bus to become free before doing so.

The greater the number of cores in a network-on-chip design, the greater quality of service

(QoS) problems arise. As such, network-on-chip architectures suffer the same problems as networks, such as fairness and throughput [8].

Figure 2.3: A multiprocessor network-on-chip architecture with 16 processing nodes. Nodes are connected in a grid formation with routers and links. Image source: [2].

Project Overview

3.1	Project Deliverables	16
3.1.1	Core Deliverables (CD)	16
3.1.2	Extended Deliverables (ED)	17
3.2	Project Timeline	18
3.2.1	Project Stages	18
3.2.2	Project Stage Detail	18
3.2.3	Timeline	20
3.3	Resources	20
3.3.1	Hardware Resources	21
3.3.2	Software Resources	21
3.4	Legal and Ethical Considerations	22

This chapter discusses the the project’s requirements, goals, and structure.

3.1 Project Deliverables

The project’s deliverables are split into two sections: core deliverables (CD) – each deliverable must be satisfied for the project to be a minimum viable product (MVP), and extended deliverables (ED) – deliverables that are not required for a MVP – features that only improve upon an existing feature.

3.1.1 Core Deliverables (CD)

The project’s core deliverables are described below.

CD1 Design a compact 16-bit RISC instruction set architecture.

The instruction set will be the primary interface to control the processor from software. An instruction set will be required to implement the custom multi-core communication interface.

It was decided to design a new instruction set rather than to extend an existing architecture as this will increase my knowledge of the constraints to consider when designing instruction sets and processors.

CD2 Design and implement a Verilog RISC core that implements the ISA in CD1.

The Verilog RISC core will be able to run software program written for the instruction set architecture.

CD3 Design and implement an on-chip interconnect for multi-core processing (2 to 32 cores) using the RISC core from CD2.

The interconnect will be a chief requirement to enable multi-core communication. The interconnect should support up to 32 cores, however FPGA implementation constraints may limit this due to limited resources.

The interconnect will control communication between the cores to enable software parallelism.

CD4 Analyse performance of serial and parallel software algorithms, such as parallel DFT, on the processor.

To evaluate the effectiveness of the developed solution, a serial and parallel implementation of a simple computing algorithm (parallel reduction, sorting) will be ran on the processor and it's performance analysed. Effectiveness will be rated on total algorithm run-time and the speed-up gained by adding more cores.

CD5 Allow the RISC core to be easily compiled to multiple FPGA vendors (Xilinx, Altera).

The developed solution should be generic and portable to allow it to be used across a wide-range of FPGA vendors and devices.

Verilog is a generic implementation-independent hardware-description language and so designing implementation specific modules is recommended.

A key consideration for this requirement is to consider the varying hard IP provided by the FPGA vendors (such as BRAM, ethernet, and PCIe [9, 10]). To overcome this problem, the developed Verilog code will conditionally compile where vendor specific requirements are present.

3.1.2 Extended Deliverables (ED)

The project's extended deliverables are described below.

ED1 Design a RISC core with an instructions-per-clock (IPC) rating of at least 1.0 (a single-cycle CPU).

ED2 Design a RISC core with a pipe-lined data path to increase the design's clock speed.

ED3 Design a scalable multi-core interconnect supporting arbitrary (more than 32) RISC core instances (manycore) using Network-on-Chip (NoC) architecture.

ED4 Design a compiler-backend for the PRCO304 [11] compiler to support the ISA from CD1. This will make it easier to build complex multi-core software for the processor.

ED5 The RISC core can communicate to peripherals via a memory-mapped addresses using the Wishbone bus.

ED6 Implement various memory-mapped peripherals such as UART, GPIO, LCD, to aid visual representation of the processor during the demonstration viva.

ED7 Store instruction memory in SPI flash.

ED8 Reprogram instruction memory at runtime from host computer.

ED9 Processor external debugger using host-processor link.

3.2 Project Timeline

3.2.1 Project Stages

The project is split up into many stages to aid planning and management of the project. There are 8 unique stage areas: 1. Initial project conception; 2 Basic RISC core development; 3. Extended RISC core development; 4. Multi-core development; 5. Processor quality-of-life (QoL) improvements; 6. Compiler development; 7. Demo preparation, and 8. Final report.

The project stages are shown in Table [3.1](#).

3.2.2 Project Stage Detail

Stages 1.0 through 1.2 – Research and Project Conception

These stages cover initial research of existing problems and solutions in the multiprocessor area. The instruction set architecture is also proposed that later stages will implement.

Stages 2.1 through 2.3 – Processor module Design, Implementation, and Integration

These stages cover the design, implementation, and integration of key processor core modules such as the instruction decoder, register sets and local memory. Integration of all the modules is a challenging task because some modules have both asynchronous and synchronous signals that need to be timed correctly in order for other modules to receive valid data. An example of this is the register set which has asynchronous read ports that are later clocked in the instruction decode stage.

Stages 3.1 through 3.4 – Advanced Processor Implementation

These stages add advanced features to the processor to provide a more functional product. Although these stages are classified as extended, their technical requirement to design and implement is not great and so are have time allocations in the project schedule. The extended features that these stages introduce are: pipelined processor stages – to drastically increase processor performance; provide a memory-mapped peripheral interface through the MMU; provide a Wishbone master interface to the MMU – allowing external peripherals such as GPIO and LCD displays to be utilised in a modular fashion; and to implement a cache memory for each processor core.

Stage	Title	Start Date	Days	Core	Applicable Deliverables
1.0	Research	Feb 04	7	x	
1.1	Requirement gathering/review	Feb 11	14	x	
1.1	Processor specification, architecture, ISA	Feb 18	100	x	CD1
1.2	Stage/Time Allocation Planning	Feb 25	7	x	
2.1	Decoder, Register Set, impl & integration	Feb 25	14	x	CD2
2.2	Register set impl & integration	Mar 04	14	x	CD2
2.3	Local memory impl & integration	Mar 11	14	x	CD2
3.1	Memory mapped register layout & impl	Apr 01	21		ED5
3.2	AMBA APB peripheral bus connected to MMU	Apr 08	21		ED5
3.3	Pipelined implementation and verification	Apr 15	21		ED2
3.4	Cache memory design & impl	Apr 22	28		ED2
4.1	Multi-core communication interface	TBD	TBD	x	CD3
4.2	Shared-memory controller	TBD	TBD	x	CD3
4.3	Scalable multi-core interface (10s of cores)	TBD	TBD	x	CD3
4.4	Multi-core example program (reduction)	TBD	TBD	x	CD4
5.1	SPI-FPGA interface for OTG programming	TBD	TBD		ED7
5.2	FPGA-PC interfacing	TBD	TBD		ED9
5.3	FPGA-PC debugging (instruction breakpoints)	TBD	TBD		ED9
6.1	Compiler backend for vmicro16	TBD	TBD		ED4
6.2	Compiler support for multi-core codegen	TBD	TBD		ED4
7.1	AMBA APB peripherals for demo	TBD	TBD	x	CD4
8.1	Final Report	TBD	TBD	x	

Table 3.1: Project stages throughout the life cycle of the project.

Stages 4.1 through 4.4 – Multiprocessor Functionality

These stages are dedicated to adding multiprocessor functionality using a loosely coupled architecture to the processor.

Stages 5.1 through 5.3 – Debugging Features

These stages cover debugging features and are classified as extended due to the large development time required to implement them as well as not being related to multiprocessor systems.

Stages 6.1 through 6.2 – Compiler Backends

These stages cover the implementation of a compiler backend to ease software writing and programming of the processor.

Stage 7.1 – Wishbone Peripherals

Additional Wishbone peripherals, such as SPI and timers will be added to produce a more useful multiprocessor system.

Stage 8.1 – Final Report

This stage is dedicated to the final report write-up. It is expected to be an iterative task that is active throughout the lifespan of the project.

3.2.3 Timeline

The project stages from Table 3.1 are displayed below in a Gantt chart.

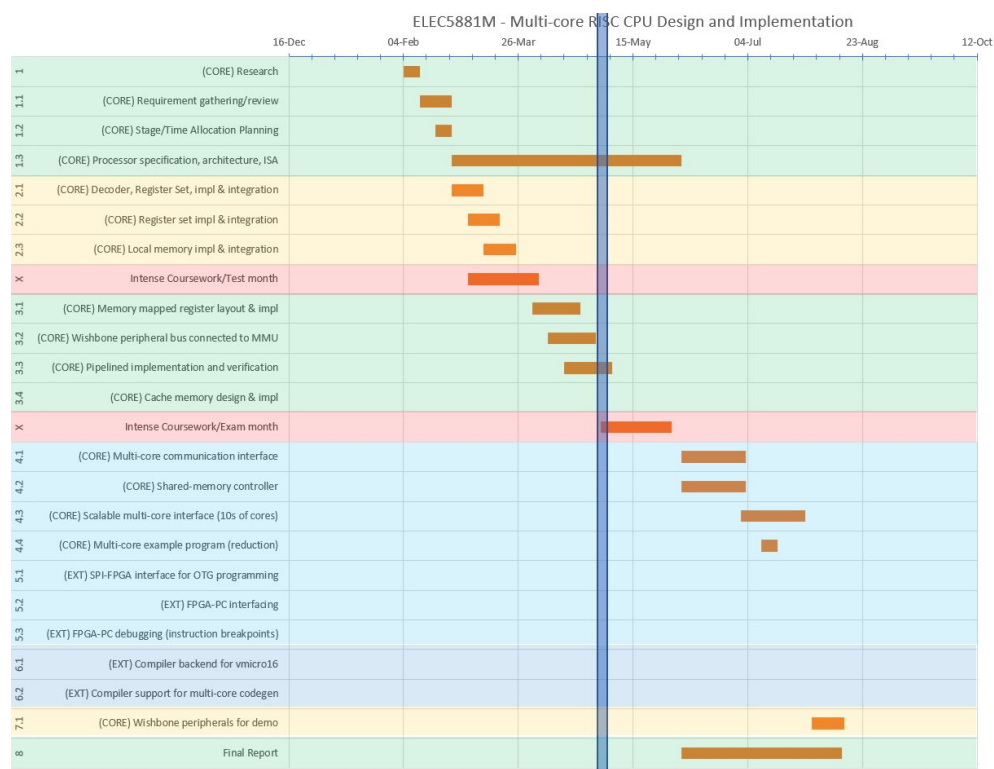

Figure 3.1: Project stages in a Gantt chart.

3.3 Resources

This section describes the hardware and software resources required to fulfil the project.

3.3.1 Hardware Resources

Core deliverable [CD5](#) requires the designed RISC core to be implemented and demonstrated on multiple FPGA devices. Although my design should synthesise for physical IC implementation, due to high costs and lengthy production times, it is not a primary development target. Due to having past experience with Xilinx FPGAs from my placement work and experience with Altera from university modules it was decided to target the Xilinx Spartan 6 XC6SLX9 and the Altera Cyclone V.

Terasic DE1-SoC Development Board

The Terasic DE1-SoC development board features a large Cyclone V FPGA and many peripherals, such as seven-segment displays, 64 MB SDRAM, ADCs, and buttons and switches, which will aid demonstration of the project. The development board is available through the university so the cost is negligible. [Figure 3.2](#) shows the peripherals (green) available to the FPGA.

Figure 3.2: Terasic DE1-SoC development board featuring the Altera Cyclone V FPGA and many peripherals. Image source: [\[3\]](#).

Minispartan 6+ FPGA Development Board

The Minispartan 6+ is a hobbyist FPGA development board with fewer peripherals than the DE1-SoC. The board features a Xilinx Spartan 6 XC6SLX9 which has far fewer resources than the DE1-SoC's Cyclone V however it's simplicity and my familiarity with Xilinx's software suite will speed up development. The development board is shown in [Figure 3.3](#).

3.3.2 Software Resources

Intel Quartus

Intel Quartus Prime is a paid-for SoC, CPLD, and FPGA software suite targeting Intel's Stratix, Arria, and Cyclone based FPGAs. The university provides student licences which will be used

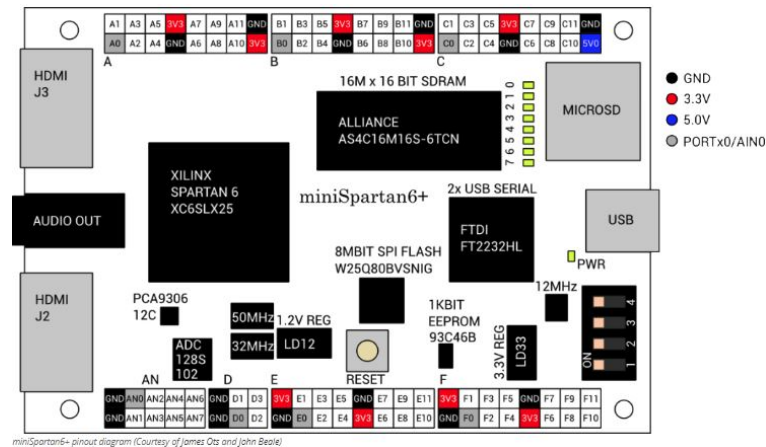

Figure 3.3: Minispartan-6+ development board featuring the Xilinx Spartan 6 XC6SLX9. Note that the XC6SLX9 and XC6SLX25 FPGAs share the same board. Image source: [4].

via VPN.

Xilinx ISE Webpack

Xilinx ISE Webpack is Xilinx's free software suite for FPGA development for Spartan 6 based FPGAs. Due to ISE's intuitive and fast work flow, most of the initial simulation and verification processes will be performed using ISE. This will greatly improve development times.

Verilator

Verilator is an open-source Verilog to C++ transpiler which provides a C++ interface to simulate Verilog modules and read/write values similar to a test bench. Verilator will be used for specific modules within the RISC core such as the ALU and decoder as Verilator is useful when performing exhaustive verification.

3.4 Legal and Ethical Considerations

The RISC core is designed to be used as an academic research and educational tool to aid learning and understanding of RISC and multi-core machines. It should not be use for roles where mission critical or safety is a factor.

The processor does not provide any memory protection features and any software running on the processor has full access to all memory.

The processor does not store/track/predict software instructions. The processor uses pipelining techniques to improve performance which results in future instructions entering the pipeline even if the software's logical sequence does not include these instructions. This could result in security vulnerabilities similar to Intel's Spectre vulnerability [12].

4.1 Introduction

While the majority of this report will focus on the multi-processing functionality of this project, it is important to understand the design decisions of the single core to understand the features and limitations of the multi-core system-on-chip as a whole.

4.2 Design and Implementation

The single-core design is a traditional 5-stage RISC processor (fetch, decode, execute, memory, write-back). The core uses separate instruction and data memories in the style of a Harvard architecture.

To satisfy [CD5](#), the Verilog code will be self-contained in a single file. This reduces the hierarchical complexity and eases cross-vendor project set-up as only a single file is required to be included.

Figure 4.1: Vmicro16 RISC 5-stage RTL diagram showing: instruction pipelining (data passed forward through clocked register banks at each stage); branch address calculation; ALU operand calculation (rd2 or imm); and program counter incrementing.

A small reduction in size within the single-core will result in substantial size reductions in

4.2.1 Instruction Set Architecture

Core deliverable **CD1** details the background for the requirement of a custom instruction set architecture. The 16-bit instruction set listing is shown in [Figure B.2](#).

In this proposed architecture, most instructions are *destructive* meaning that source operands also act as the destination, hence effectively *destroying* the original source data. This design

decision reduces the complexity of the ISA as traditional three operand instructions, for example `add r0, r0, r1`, can be encoded using only two operands `add r0, r1`. However, this does increase the complexity of compilers as they may need to make temporary copies of registers as the instructions will *destroy* the original source data.

The instruction set is split into 7 categories (highlighted by colours in [Figure B.2](#)):

- Special instructions, such as halting and interrupt returns;
- Bitwise operations, such as XOR and AND;
- Signed arithmetic;
- Unsigned arithmetic;
- Conditional branches and compare instructions;
- and Load/store instructions, with their atomic equivalents.

4.2.2 Memory Management Unit

It was decided to use a memory management unit (MMU) to make it easier and extensible to communicate with external peripherals or additional registers. This method transparently uses the existing `LW[EX]` / `SW[EX]` to easily provide an arbitrary number of peripherals/special purpose addresses to the software running on the processor.

4.2.3 Instruction and Data Memory

The design uses separate instruction and data memories similar to a Harvard architecture computer. This architecture was chosen due because it is generally easier to implement, however later resulted in design challenges in large multi-core designs. This is discussed later in the report.

Each single-core has it's own *scratch* memory – a small RAM-like memory which can be used for stack-space and arrays too large to fit into the 8 registers. These memories are provided as is – meaning it's up to the software to implement and provide any stack-frame, function, and calling, functionality. Each core also features it's own read-only instruction memory that is programmed at compile time of the design, or via the UART0 reciever interface (discussed later). Both of these memories map onto synchronous, read-first, single-port, FPGA block RAMs to minimise LUT requirements.

Users can customise the size of these memories by tweaking the following parameters in the `vmicro16_soc_config.v` file: `DEF_MEM_INSTR_DEPTH` for the instruction memory, and `DEF_MEM_SCRATCH_DEPTH` for the scratch memory.

4.2.4 ALU Design

The Vmicro16's ALU is an asynchronous module that has 3 inputs: data a; data b; and opcode `op`; and outputs data c. The ALU is able to operate on both register data (`rd1` and `rd2`) and

immediate values. A switch is used to set the *b* input to either the *rd2* or *imm* value from the previous stage.

Figure 4.2: Vmicro16 ALU diagram showing clocked inputs from the previous IDEX stage being

The ALU also performs comparison (CMP) operations in which it returns flags similar to X86's overflow, signed, and zero, flags. The combination of these flags can be used to easily compute relationships between the two input operands. For example, if the zero flag is not equal to the signed flag, then the relationship between inputs *a* and *b* is that $a < b$.

```

1  module branch (
2      input [3:0] flags,
3      input [7:0] cond,
4      output reg en
5  );
6      always @(*)
7          case (cond)
8              `VMICRO16_OP_BR_U: en = 1;
9              `VMICRO16_OP_BR_E: en = (flags[`VMICRO16_SFLAG_Z] == 1);
10             `VMICRO16_OP_BR_NE: en = (flags[`VMICRO16_SFLAG_Z] == 0);
11             `VMICRO16_OP_BR_G: en = (flags[`VMICRO16_SFLAG_Z] == 0) &&
12                 (flags[`VMICRO16_SFLAG_N] == flags[`VMICRO16_SFLAG_V]);
13             `VMICRO16_OP_BR_L: en = (flags[`VMICRO16_SFLAG_Z] != flags[`VMICRO16_SFLAG_N]);
14             `VMICRO16_OP_BR_GE: en = (flags[`VMICRO16_SFLAG_Z] == flags[`VMICRO16_SFLAG_N]);
15             `VMICRO16_OP_BR_LE: en = (flags[`VMICRO16_SFLAG_Z] == 1) ||
16                 (flags[`VMICRO16_SFLAG_N] != flags[`VMICRO16_SFLAG_V]);
17             default: en = 0;
18         endcase
19     endmodule

```

Listing 1: ALU branch detection using flags: zero (Z), overflow (V), and negative (N).

The Verilog implementation of the ALU is shown in Listing 2. The ALU's asynchronous output is clocked with other registers, such as destination register *rs1* and other control signals, in the EXME register bank.

```

1  always @(*) case (op)
2      // branch/nop, output nothing
3      `VMICRO16_ALU_BR,
4      `VMICRO16_ALU_NOP:      c = {DATA_WIDTH{1'b0}};
5      // load/store addresses (use value in rd2)
6      `VMICRO16_ALU_LW,
7      `VMICRO16_ALU_SW:      c = b;
8      // bitwise operations
9      `VMICRO16_ALU_BIT_OR:   c = a | b;
10     `VMICRO16_ALU_BIT_XOR:  c = a ^ b;
11     `VMICRO16_ALU_BIT_AND:  c = a & b;
12     `VMICRO16_ALU_BIT_NOT:   c = ~(b);
13     `VMICRO16_ALU_BIT_LSHFT: c = a << b;
14     `VMICRO16_ALU_BIT_RSHFT: c = a >> b;

```

Listing 2: Vmicro16's ALU implementation named vmicro16_alu. vmicro16.v

4.2.5 Decoder Design

Instruction decoding occurs in the between the IFID and IDEX stages. The decoder extracts register selects and operands from the input instruction. The decoder outputs are asynchronous which allows the register selects to be passed to the register set and register data to be read asynchronously. The register selects and register read data is then clocked into the IDEX register bank.

```

1  always @(*) case (instr[15:11])
2      `VMICRO16_OP_BR:      alu_op = `VMICRO16_ALU_BR;
3      `VMICRO16_OP_MULT:    alu_op = `VMICRO16_ALU_MULT;
4
5      `VMICRO16_OP_CMP:     alu_op = `VMICRO16_ALU_CMP;
6      `VMICRO16_OP_SETC:    alu_op = `VMICRO16_ALU_SETC;
7
8      `VMICRO16_OP_BIT:     casez (instr[4:0])
9          `VMICRO16_OP_BIT_OR:      alu_op = `VMICRO16_ALU_BIT_OR;
10         `VMICRO16_OP_BIT_XOR:     alu_op = `VMICRO16_ALU_BIT_XOR;
11         `VMICRO16_OP_BIT_AND:     alu_op = `VMICRO16_ALU_BIT_AND;
12         `VMICRO16_OP_BIT_NOT:     alu_op = `VMICRO16_ALU_BIT_NOT;
13         `VMICRO16_OP_BIT_LSHFT:   alu_op = `VMICRO16_ALU_BIT_LSHFT;
14         `VMICRO16_OP_BIT_RSHFT:   alu_op = `VMICRO16_ALU_BIT_RSHFT;
15     default:                alu_op = `VMICRO16_ALU_BAD; endcase

```

Listing 4: Vmicro16's decoder module code showing nested bit switches to determine the intended opcode. vmicro16.v

In Listing 4, it can be seen that the first 4 opcode cases (BR, MULT, CMP, SETC) are represented using the same 15-11 (opcode) bits, however the BIT instructions share the same opcode and so require another bit range to be compared to determine the output function.

4.2.6 Pipelining

In the interim progress update, the processor design featured *instruction pipelining* to meet requirement ED1. Instruction pipelining allows instructions executions to be overlapped in the pipeline, resulting in higher throughput (up to one instruction per clock) at the expense of 5-6 clocks of latency and *significant* code complexity. As the development of the project shifted from single-core to multi-core, it became obvious that the complexity of the pipelined processor would inhibit the integration of the multi-core functionality. It was decided to remove the instruction pipelining functionality and use a simpler state-machine based pipeline that is much simpler to extend and would cause fewer challenges later in the project.

4.2.7 Design Optimisations

In a design that has many instantiations of the same component, a small resource saving improvement within the component can have a significant overall savings improvement if it is instantiated many times. Project requirement [CD5](#) requires the design to be compiled for a range of FPGA sizes, and so space saving optimisations are considered.

Register Set Size Improvements

A register set in a CPU is a fast, temporary, and small memory that software instructions directly manipulate to perform computation. In the Vmicro16 instruction set, eight registers named r0 to r7 are available to software. The instruction set allows up to two registers to be references in most instructions, for example the instruction `add r0, r1` tells the processor to perform the following actions:

- Clock 1.** Fetch r0 and r1 from the register set
- Clock 2.** Add the two values together in the ALU
- Clock 3.** Store the result back the register set in r0

For Clock 1, it was originally decided to use a dual port register set (meaning that two data reads can be performed in a single clock, in this case r0 and r1), however due to the asynchronous design of the register set (for speed) the RTL produced consumed a significant amount of FPGA resources, approximately 256 flip-flops ($16 \text{ (data width)} * 8 \text{ (registers)} * 2 \text{ (ports)}$). To reduce this, it was decided to split task 1 into two steps over two clock cycles using a single-port register set. This required the processor pipe-line to use another clock cycle resulting in slightly lower performance, however the size improvements will allow for more cores to be instantiated in the design. This optimisation is also applied to the interrupt register set, resulting in a saving of approximately 256 flip-flops per core (128 in the normal mode register set, and 128 in the interrupt register set). As shown, adding a single clock delay saves a significant amount of LUTs. This saving will be amplified in designs with many cores.

4.3 Interrupts

Interrupts are a technique used by processors to run software functions when an event occurs within the processor, such as exceptions, or signalled from an external source, such as a UART receiver signalling it has received new data. Today, it is common for micro-controllers, soft-processors, and desktop processors, to all feature interrupts. Modern implementations support an *interrupt vector* which is a memory array that contains addresses to different *interrupt handlers* (a software function called when a particular interrupt is received).

Although interrupts are not a requirement for a multi-core system, it was decided to implement this functionality to boost my understanding of such systems. In addition, example demos provided with this project are better visualised with a interrupt functionality.

4.3.1 Overview

The interrupt functionality in this project supports the following:

- Per-core 8 cell interrupt vector accessible to software.
Software programs running on the Vmicro16 processor can edit the interrupt vector to add their own interrupt handlers at runtime.
- Fast context switching.
A dedicated interrupt register set is multiplexed with the normal mode register set to provide faster context switching. It should be noted that only the registers are saved during a context switch. This means that the stack is not saved. A schematic of the register multiplex is shown in [Figure B.1](#).
- Parametrised interrupt sources and widths.
Users can configure the width of the interrupt in signals and the data width per interrupt source via the `vmicro16_soc_config.v`. By default, 8 interrupt sources are available and each can provide 8-bits of data.

4.3.2 Hardware Implementation

Context Switching

When acting upon an incoming interrupt the current state the processor must be saved so that changes from the interrupt handler, such as register writes and branches, do not affect the current state. After the interrupt handler function signals it has finished (by using the *Interrupt Return* INTR instruction) the saved state is restored. In the case of the Vmicro16 processor, the program counter `r_pc[15:0]` and register set `regs` instance are the only states that are saved. Going forth, the terms *normal mode* and *interrupt mode* are used to describe what registers the processor should use when executing instructions.

When saving the state, to avoid clocking 128 bits (8 registers of 16 bits) into another register (which would increase timing delays and logic elements), a dedicated register set for the interrupt mode (`regs_isr`) is multiplexed with the normal mode register set (`regs`). Then depending on the mode (identified by the register `regs_use_int`) the processor can easily switch between the two large states without significantly affecting timing.

The timing diagram in [Figure 4.3](#) shows the behavioural logic for the TIMR0 interrupt source.

Figure 4.3: Time diagram showing the TIMR0 peripheral emitting a 1us periodic interrupt signal (out) to the processor. The processor acknowledges the interrupt (int_pending_ack) and enters the interrupt mode (regs.use_int) for a period of time. When the interrupt handler reaches the Interrupt Return instruction (indicated by w_intr) the processor returns to normal mode and restores the normal state.

4.3.3 Software Interface

A memory-mapped software interface is provided through the MMU to allow easy software control of the interrupt behaviour. The interface is provided at the address range 0x0100 to 0x0108. This interface is per-core allowing each core to individually control what interrupts it receives and what functions to call upon an interrupt. This enables complex functionality, such as allowing each core to execute different functions upon the same interrupt.

Figure 4.4: The interrupt vector (0x0100 - 0x0107) consists of eight 16-bit values that point to memory addresses of the instruction memory to jump to.

Interrupt Vector (0x0100-0x0107)

The interrupt vector is a per-core register that is used to store the addresses of interrupt handlers. An interrupt handler is simply a software function residing in instruction memory that is branched to when a particular interrupt is received.

Interrupt Mask (0x0108)

The interrupt mask is a per-core register that is used to mask/listen specific interrupt sources. This enables processing cores to individually select which interrupts they respond to. This allows for multi-processor designs where each core can be used for a particular interrupt

Figure 4.5: Interrupt Mask register (0x0108). Each bit corresponds to an interrupt source. 1 signifies the interrupt is enabled for/visible to the core. Bits [7:2] are left to the designer to assign. Bit 0 is assigned to TIMR0's interval timer. Bit 1 is assigned to the UART0's receiver (unassigned if DEF.USE_REPROG is enabled).

source, improving the time response to the interrupt for time critical programs. The Interrupt Mask register is an 8-bit read/write register where each bit corresponds to a particular interrupt source and each bit corresponds with the interrupt handler in the interrupt vector. The interrupt mask register is shown in [Figure 4.5](#).

Software Example

To better understand the usage of the described interrupt registers, a simple software program is described below. The following software program produces a simple and power efficient routine to initialise the interrupt vector and interrupt mask.

```

1  setup_interruptions:
2      // Set interrupt vector at 0x100
3      // Move address of isr0 function to vector[0]
4      movi    r0, isr0
5      // create 0x100 value by left shifting 1 8 bits
6      movi    r1, #0x1
7      movi    r2, #0x8
8      lshft   r1, r2
9      // write isr0 address to vector[0]
10     sw      r0, r1
11
12  enable_interruptions:
13     // enable all interrupts by writing 0x0f to 0x108
14     movi    r0, #0x0f
15     sw      r0, r1 + #0x8 // (0x100 + 0x8 = 0x108)
16     halt
17     // enter low power idle state
18
19  isr0:
20     movi    r0, #0xff // arbitrary name
21     // do something
22     intr    // return from interrupt

```

A more complex example software program utilising interrupts and the TIMR0 interrupt is described in section [D.1](#).

4.3.4 Design Improvements

The hardware and software interrupt design have changed throughout the projects cycle. In initial versions of the interrupt implementation, the software program, while waiting for an interrupt, would be in a tight infinite loop (branching to the same instruction). This resulted in the processor using all pipeline stages during this time. The pipeline stages produce many logic transitions and memory fetches which raise power consumption and temperatures. This is quite noticeable especially when running on the Spartan-6 LX9 FPGA.

To improve this, it was decided to implement a new state within the processor's state machine that, when entered, did not produce high frequency logic transitions or memory

fetches. The HALT instruction was modified to enter this state and the only way to leave is from an interrupt or top-level reset. This removes the need for a software infinite loop that produces high frequency logic transitions (decoding, ALU, register reads, etc.) and memory fetches.

4.4 Verification

Various verification techniques are employed to ensure correct operation of the processor.

The first technique involves using static assertions to identify incorrect configuration parameters at compile time, such as having zero instruction memory and scratch memory depth. These assertions use the `static_assert` for top level checks and `static_assert_ng` for checks inside generate blocks.

The second verification technique is to use assertions in always blocks to identify incorrect behavioural states. This is done using the `rassert` (run-time assert) macro.

The third verification technique is to use automatic verifying test benches. These test benches drive components of the processor, such as the ALU and decoder, and check the output against the correct value. This uses the `rassert` macro.

The final method of verification is to verify the complete design via a behavioural test bench. The design is passed a compiled software program with a known expected output, and is ran until the `r_halt` signal is raised. The test bench then checks the value on the `debug0`, `debug1`, and `debug2` signals against the expected value. If this matches, then it is assumed that sub-components of the design also operate correctly. This technique does not monitor the states of sub-components and statistics (such as time taken to execute an instruction), there leaves the possibility that some components could have entered an illegal state.

Interconnect

5.1	Introduction	33
5.1.1	Comparison of On-chip Buses	33
5.2	Overview	34
5.2.1	Design Considerations	35
5.3	Interfaces	36
5.3.1	Master to Slave Interface	36
5.3.2	Multi-master Support	37
5.4	Further Work	38

5.1 Introduction

The Vmicro16 processor needs to communicate with multiple peripheral modules (such as UART, timers, GPIO, and more) to provide useful functionality for the end user.

Previous peripheral interface designs of mine have been directly connected to a main driver with unique inputs and outputs that the peripheral required. For example, a timer peripheral would have dedicated wires for it's load and prescaler values, wires for enabling and resetting, and wires for reading. A memory peripheral would have wires for it's address, read and write data, and a write enable signal. This resulted in each peripheral having a unique interface and unique logic for driving the peripheral, which consumed significant amounts of limited FPGA resources.

It can be seen that many of the peripherals need similar inputs and outputs (for example read and write data signals, write enables, and addresses), and because of this, a standard interface can be used to interface with each peripheral. Using a standard interface can reduce logic requirements as each peripheral can be driven by a single driver.

5.1.1 Comparison of On-chip Buses

The choice of on-chip interconnect has changed multiple times over the life-cycle of this project, primary due to ease of implementation and resource requirements.

Originally, it was planned to use the Wishbone bus [?] due to it's popularity within open-source FPGA modules and good quality documentation.

Late in the project, it was decided to use the AMBA APB protocol [?] as it is more commonly used in large commercial designs and understanding how the interface worked would better benefit myself. APB describes an intuitive and easy to implement 2-state interface aimed at communicating with low-throughput devices, such as UARTs, timers, and watchdogs.

Figure 5.1: Waveform showing an APB read transaction.

5.2 Overview

The system-on-chip design is split into 3 main parts: peripheral interconnect (red), CPU array (gray), and the instruction memory interconnect (green).

A block diagram of this project is shown in [Figure 5.2](#)

Figure 5.2: Block diagram of the Vmicro16 system-on-chip.

5.2.1 Design Considerations

There are several design issues to consider for this project. These are listed below:

- **Design size limitations**

The target devices for this project are small to medium sized FPGAs (featuring approximately 10,000 to 30,000 logic cells). Because of this, it is important to use a bus interconnect that has a small logic footprint yet is able to scale reasonably well.

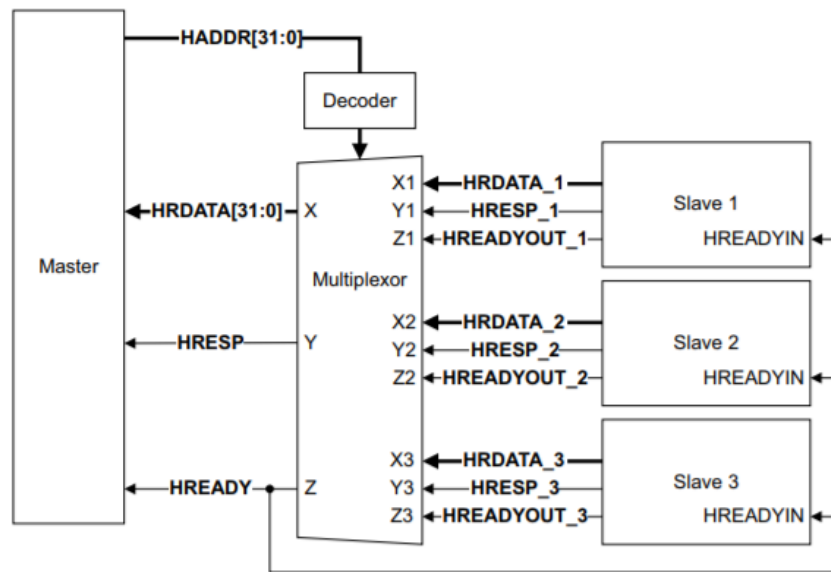

- **Ease of implementation**

The interconnect and any peripherals should be easy to implement within the time allocations specified in Figure 3.1.

- **Scalable**

The interconnect should allow for easy scalability of master and slave interfaces with minimal code changes.

5.3 Interfaces

5.3.1 Master to Slave Interface

20	19	18	17	16	15											0
LE	SE	CORE_ID			Address											PADDR[20:0]
					Write data											PWDATA[15:0]
					Read Data											PRDATA[15:0]
															WE	PWRITE[0:0]
															EN	PENABLE[0:0]

5.3.2 Multi-master Support

In this design, each processor can act as an APB master to communicate with peripherals, for example to write a value to UART or to the shared memory peripheral. Because each core runs independently from other cores, it is likely, especially in many-core systems, that two or more processors will want to use the peripheral bus at the same time.

As the peripheral and instruction interconnects use a shared one-to-many (one master to many slaves) bus architecture, only one master can use the bus at any-time. To enable multiple masters to use the bus, a device called an *arbiter* must be used to control which master gets access to drive the shared interconnect.

Arbiters can vary in complexity, mostly relative to throughput requirements.

An ideal arbiter for this interconnect, which ideally features many, possibly tens of, high-throughput masters, would likely feature a priority-based and pipelined arbiter with various devices to improve performance such as cache-coherencies.

Overview

Due to this project's limited time, and my personal knowledge in this area, a simple rotating arbiter is used. This arbitration scheme is likely the simplest that can be thought of. A schematic of arbiter interconnect is shown in [Figure 5.3](#).

In this scheme, access to the bus is given incrementally to each master port, even if the master port has not requested to use the bus. The active master port can use the bus for as long as it requires, and signals it has finished by lowering the PSEL signal. When the PSEL signal is lowered, the arbiter grants access to the next master port. If this next master port has not raised its PSEL signal (i.e. it has not requested access to the bus) then the arbiter grants access to the next master port, and so on. In Verilog, this is simply an incremental counter which is used to index the master ports array. To support a variable number of master ports, the width of each APB signal is multiplied by the number of cores, as shown in [Listing 7](#).

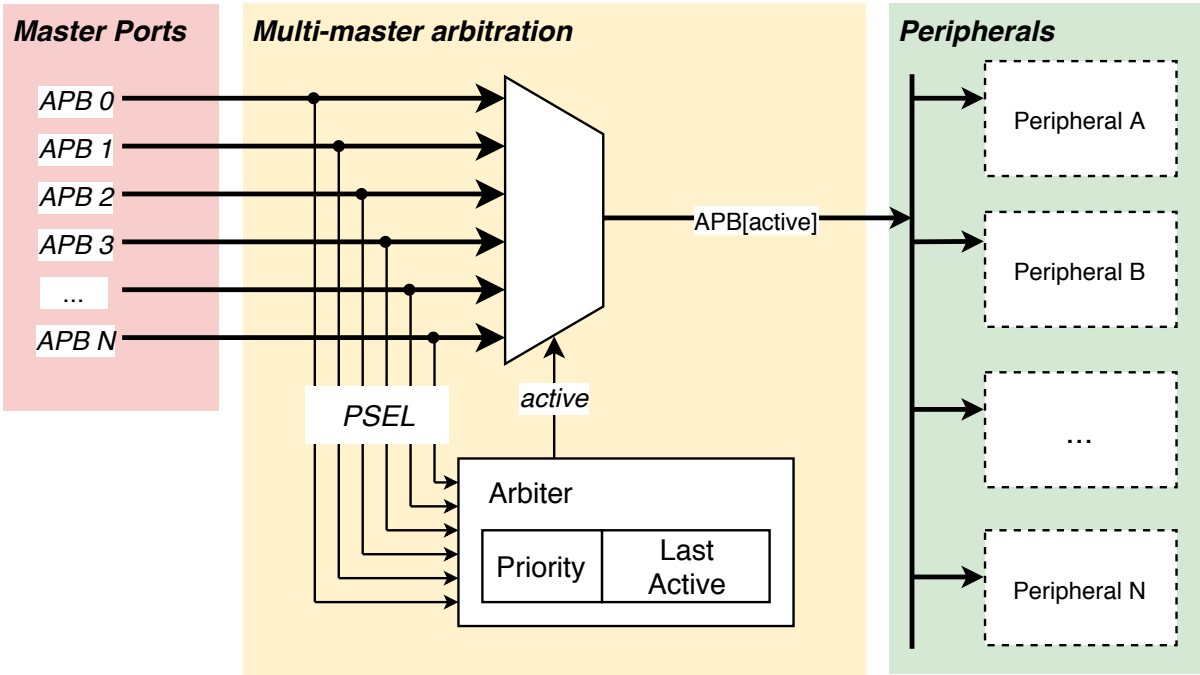

Figure 5.3: Foo

83	62	41	20	0
Core N-1	...	Core 1	Core 0	

5.4 Further Work

The submitted design is acceptable for a multi-core system as it fulfils the following requirements:

- Support an arbitrary number of peripherals.
- Supports memory-mapped address decoding.
- Supports multiple master interfaces.

Arbiter Performance Improvements

However, it fails in the performance aspect. A one clock penalty occurs if the next master port has not requested the bus. This may seem a small price to pay for such a simple arbiter design, however it can add up significantly in many-core designs. For example, if core #0 performs some action on the bus, but core #10 is the next master that wants to use the bus, then the arbiter will waste time incremental granting access to cores #1 to #9 which do not need the bus. This is also made worse when one of the cores is blocking access to a peripheral resource, such as through a mutex or semaphore.

To overcome this penalty, a scheme could use an algorithm to find the next master port requesting access, and grant access directly to it when the current master has finished. Another scheme could be to use a priority encoder. Here, a hard-coded lookup table (LUT) could be used, where the inputs are each master port’s PSEL signal (acting as a bus request line) and

the output being which master to grant access to. As this is targetting FPGA devices, this implemented would require few LUT resources for the arbiter, due to the hard-coded LUT approach. An example of this is given in M. Weber's *Arbiter: Design Ideas and Coding Styles* [13, p. 2].

APB Bus Errors and Recovery

This project's implementation of a multi-master APB interconnect does not provide a method of detecting errors and stalls. This is mainly due to time constraints.

An easy error that could be detected is PADDR addresses that do not fall into a memory-mapped address range. This can easily and cheaply be detected in the address decoding module. This will be discussed in detail in the next chapter.

As previously stated, the active bus master can take control of the bus for as long as it wants to. This is useful for high-throughput transactions, such as memory operations to global memory, but detecting a stalled or glitched operation is not immediately identifiable. If an active master stalls or glitches, it may not be able to lower the PSEL line which appears to the arbiter that the transaction is still happening normally. To overcome this, a timer could be used to detect stalled operations and reset the affected peripheral (essential a watchdog but for an interconnect).

Chapter 6

Memory Mapping

6.1	Introduction	40
6.2	Address Decoding	40
6.2.1	Decoder Optimisations	41
6.3	Memory Map	43

The Vmicro16 processor uses a memory-mapping scheme to communicate with peripherals and other cores. This chapter describes the design decisions and implementation of the memory-map used in this project.

6.1 Introduction

Memory mapping is a common technique used by CPUs, micro-controllers, and other system-on-chip devices, that enables peripherals and other devices to be accessed via a memory address on a common bus. In a processor use-case, this allows for the reuse of existing instructions (commonly memory load/store instructions) to communicate with external peripherals with little additional logic.

6.2 Address Decoding

An address decoder is used to determine the peripheral that the address is requesting. The address decoder module, `addr_dec` in `apb_intercon.v`, takes the 16-bit `PADDR` from the active APB interface and checks for set bits to determine which peripheral to select. The decoder outputs a chip enable signal `PSEL` for the selected peripheral. For example, if bit 12 is set in `PADDR` then the shared memory peripheral's `PSEL` is set high and others to low. A schematic for the decoder is shown in [Figure 6.1](#).

Figure 6.1: Schematic showing the address decoder (*addr_dec*) accepting the active PADDR signal and outputting PSEL chip enable signals to each peripheral.

6.2.1 Decoder Optimisations

Performing a 16-bit equality comparison of the PADDR signal against each peripheral memory address consumes a significant amount of logic. Depending on the synthesis tools and FPGA features, a 16-bit comparator might require a fixed 16-bit value input to compare against (where the 0s are inverted) and a wide-AND to reduce and compare [14, 15]. An example 4-bit comparator is shown below in Figure 6.2.

Figure 6.2: Example 4-bit binary comparator which compares the bits (a, b, c, d) to the constant value 1010. The 0s of the constant are inverted and then all are passed to a wide-AND.

As we are targeting FPGAs, which use LUTs to implement combinatorial logic, we can conveniently utilise Verilog's `==` operator on fairly large operands without worrying about consuming too many resources. The targeted FPGA devices in this project, the Cyclone V and Spartan 6, feature 6-input LUTs which allow 64 different configurations [16, 17]. Knowing this, we can design the address decoder to utilise the FPGA's LUTs more effectively and reduce its footprint significantly.

We can use part of the PADDR signal as a chip select and the other bits as sub-addresses to interface with the peripheral. The addressing bits are passed into the FPGA's 6-input LUTs which are programmed (via the bitstream) to output 1 or 0 depending on the address. Figure 6.3 below shows a LUT based approach to address decoding which will utilise approximately one ALM/CLB module per peripheral chip select (PSEL) and one for error detection. This method

of comparison (LUT based) is utilised in the `addr_dec` module in `apb_intercon.v`.

Figure 6.3: Bits [7:3] of an 8-bit `PADDR` signal are used as inputs to 5-bit LUTs to generate a `PSEL` signal. In addition, a default error case is shown allowing the address decoder to detect incorrect `PADDR` values (e.g. if no `PSEL` signals are generated).

The address decoding methods discussed above are examples of *full-address* decoding, where each bit (whether required or not) is compared. It is possible to further reduce the required logic by utilising *partial-address* decoding [18]. Partial-address decoding can reduce logic requirements by not using all bits. For example, if bits in address `0x0100` do not conflict with bits in other addresses (i.e. bit 8 is high in more than 1 address), then the address decoder needs only concern bit 8, not the other bits. This is visualised in Figure 6.4 below. This method is utilised in the MMU's address decoder (module `vmicro16_mmu` in `vmicro16.v`:181). As this is an optimisation per core, significant resources can be saved when a large number of cores are used.

Figure 6.4: Partial address decoding used by the Vmicro16 SoC design. Each peripheral shown only needs to decode a signal bit to determine if it is enabled.

6.3 Memory Map

The system-on-chip's memory map is shown below in [Figure 6.5](#). The addresses for each peripheral have been carefully chosen for both:

- Easy software access – creating addresses via software requires few instructions (normally one to four MOVI and LSHIFT instructions to address 0x0000 to 0xffff), which increases software performance.
- and Reducing address decoding logic – most addresses can be decoded using partial decoding techniques.

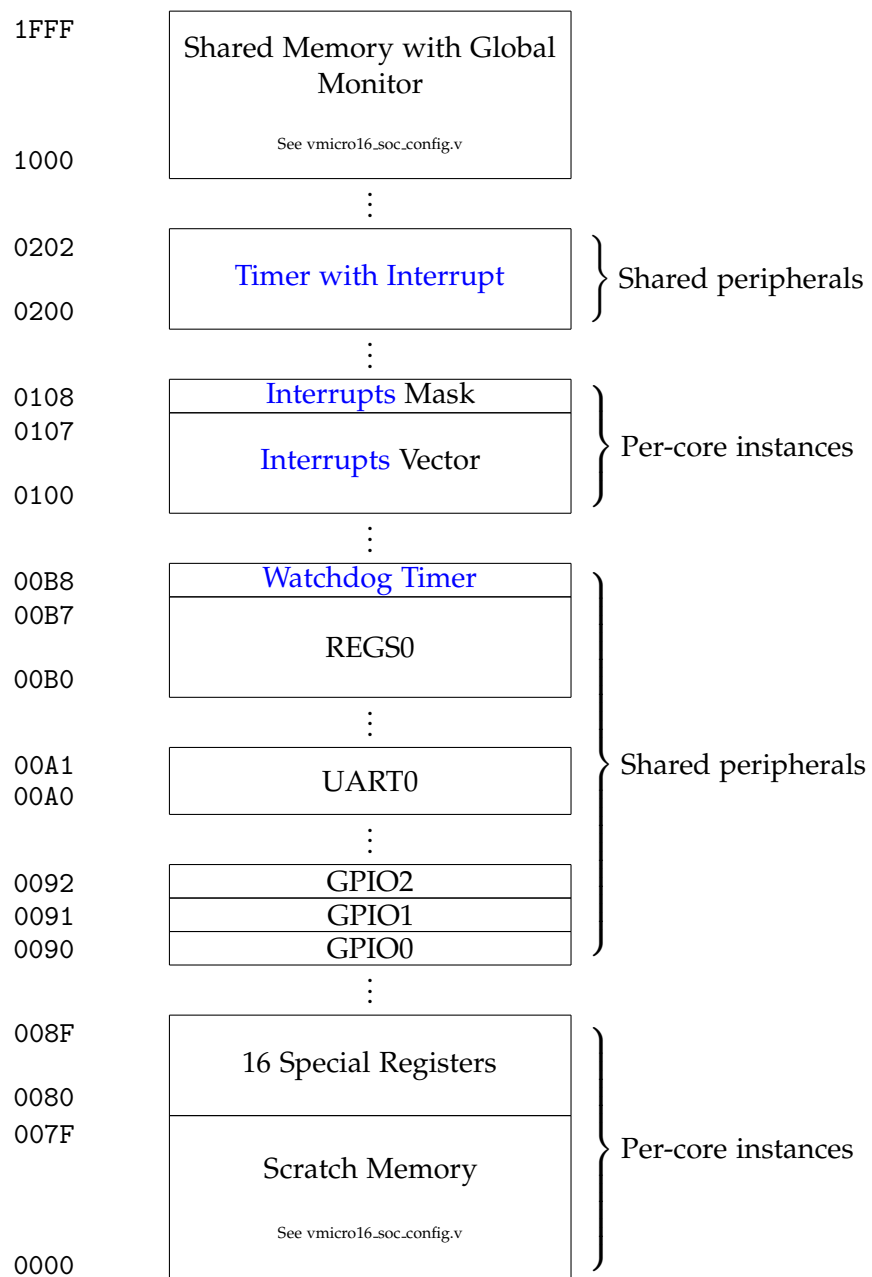

Figure 6.5: Memory map showing addresses of various memory sections.

Chapter 7

Multi-core Communication

7.1	Introduction	44
7.1.1	Design Goals	44
7.1.2	Context Identification	44
7.1.3	Thread Synchronisation	45

So far we have discussed the features and design of the Vmicro16 system-on-chip. This section will discuss the multi-processing functionality and how to use it.

7.1 Introduction

Multi-processing functionality is the primary deliverable of this project.

7.1.1 Design Goals

- **Support common synchronisation primitives.**

Software should be able to implement common synchronisation primitives, such as mutexes, semaphores, and memory barriers, to perform atomic operations and avoid race conditions, which are critical in parallel and concurrent software applications.

- **Context identification.**

The SoC should expose configuration information such as: the number of processing cores, amount of shared and scratch memory, and the `CORE_ID`, to each thread.

7.1.2 Context Identification

A goal of the multi-processing functionality of this project is allow software written for it to be run on any number of cores. This means that a software program will scale to use all cores in the SoC without needing to rewrite the software. To enable this functionality, the software must be able to read contextual information about the SoC, such as the number of cores, how much global and scratch memory is available, and what the `CORE_ID` of the current core is.

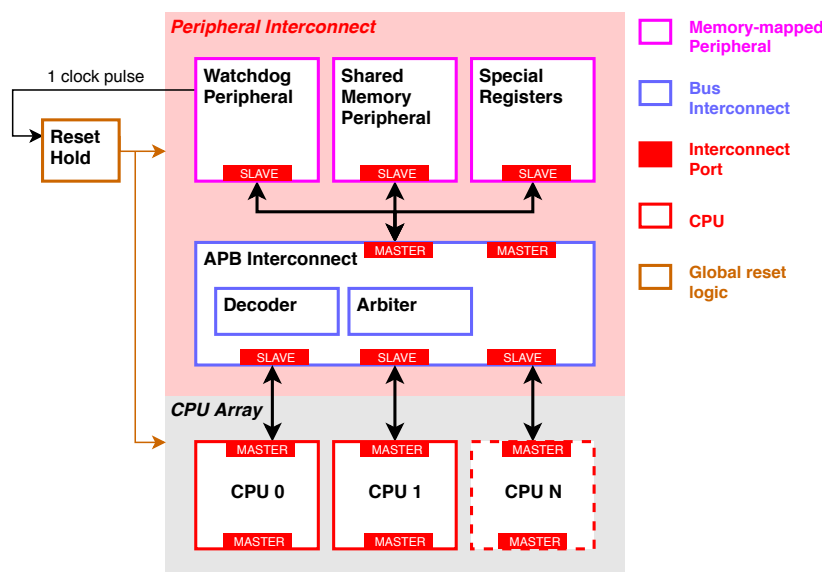

Figure 7.1: Block diagram showing the main multi-processing components: the CPU array and a peripheral interconnect used for core synchronisation.

This information is provided through the Special Registers peripheral (0x0080 - 0x008F), shown in Figure 7.1. This register set provides relevant information for writing software that can dynamically scale for various SoC configurations.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

User defined																008F RW

Figure 7.2: Vmicro16 Special Registers layout (0x0080 - 0x008F).

7.1.3 Thread Synchronisation

Mutexes

In software, a mutex is an object used to control access to a shared resource. The term *object* is used as its implementation is normally platform dependant, meaning that the processor may provide a hardware mechanism or is left for the operating system to provide.

In this project, mutexes are provided by the processor through the Shared Memory Peripheral (0x1000 to 0x1FFF) which provides a large RAM-style memory accessible by all cores through the peripheral interconnect bus. This large memory is explicitly defined to use the FPGA's BRAM blocks using Xilinx's Verilog `ram_style="block"` attribute to avoid wasting LUTs when using high core counts. The peripheral allows each memory cell to be *locked*,

meaning that only the cell owner can modify it's contents. This is implemented by using another large memory, `locks`, to store the `CORE_ID + 1` of the owner, as shown in Listing 5. In this system, a lock containing the value 0 indicates an unlocked cell. As `CORE_ID`s are indexed from zero, 1 is arithmetically added to each cell. For example, if core #2 wants to lock a memory cell, the value 3 is written to the lock.

```

1  reg [15:0]      ram    [0:8191]; // 16KB large RAM memory
2  reg [clog2(CORES):0] locks [0:8181]; // memory cell owner

```

Listing 5: RAM and lock memories instantiated by the shared memory peripheral.

To lock and unlock cells, the instructions `LWEX` and `SWEX` instructions are used. These instructions are similar to the `LW/SW` instructions but provide locking functionality. The `EX` in the instruction names indicate *exclusive access*. `LWEX` is used to read memory contents (like `LW`) and also lock the cell if not already locked. If a core attempts to lock an already locked cell, the lock does not change. Unlocking is done by the `SWEX` instruction, which conditionally writes to the memory cell if it is locked by the same core. Unlike `SW`, `SWEX` returns a zero for success and one for failure if it is locked by another core.

Figure 7.3 shows a simple assembly function to lock a memory cell.

```

1  lock_mutex:
2      // attempt lock
3      lwex r0, r1
4      // check success
5      swex r0, r1
6      cmp r0, r3
7      // if not equal (NE), retry
8      movi r4, lock_mutex
9      br r4, BR_NE
10 critical:
11     // core has the mutex

```

Figure 7.3: Assembly code for locking a mutex. `r1` is the address to lock. `r3` is zero. `r4` is the branch address.

Barriers

Barriers are a useful software sequence used to block execution until all other threads (or a subset) have reached the same point. Barriers are often used for broadcast and gather actions (sending values to each core or receiving them). They are also used to synchronise program execution if some threads have more work to do than others.

The Vmicro16 processor provides barrier synchronisation through the Shared Memory Peripheral. Like the mutex code, the barrier code uses the `LWEX` and `SWEX` instructions to lock a memory cell. Instead of immediately checking the lock as an abstract object, the barrier code treats the cell as a normal memory cell containing a numeric value. Listing 6 shows a software example of this. When the `barrier_reached` code is reached, the code will increment the shared memory value by 1, indicating that the number of threads that have reached this point has increased by one (`r5`). The `barrier_wait` function is then entered which waits until this numeric value (`r5`) is equal to the number of threads (`r7`) in the system. If this is true, then all threads have reached the `barrier_wait` function and can continue with normal program execution.

```
1  barrier_reached:
2      // load latest count
3      lwex    r0, r5
4      // try increment count
5      // increment by 1
6      addi    r0, r3 + #0x01
7      // attempt store
8      swex    r0, r5
9
10     // check success (== 0)
11     cmp     r0, r3
12     // branch if failed
13     movi    r4, barrier_reached
14     br      r4, BR_NE
15
16  barrier_wait:
17     // load the count
18     lw      r0, r5
19     // compare with number of threads
20     cmp     r0, r7
21     // jump back to barrier if not equal
22     movi    r4, barrier_wait
23     br      r4, BR_NE
```

Listing 6: Assembly code for a memory barrier. Threads will wait in the `barrier_wait` function until all other threads have reached that code point.

So far the system's design, implementation, and example usage, has been presented and discussed.

8.1 Introduction

This chapter presents analytic information

8.2 Implementation Analysis

This section analysis the synthesised and implemented system-on-chip design to see the effect of increasing core counts.

8.2.1 Design Size

Implementation

On a minimal system-on-chip configuration, with one core and minimal peripherals and features (no reprogramming, no interrupts, no UART), the design requires as few as 700 LUTs with the processor core requiring approximately 300-400 LUTs.

Memory Constraints

As discussed in [Chapter 4 Single-core Design](#), each processor core features two memories: instruction and scratch memory, which can both map onto synchronous, single-port, FPGA BRAM blocks. While this will reduce LUT requirements in designs with few cores, it becomes a non-trivial problem as the core counts increase. FPGAs have a fixed number of hard-BRAM blocks available for inference by the HDL compiler, for example the low-end Xilinx Spartan-6 XC6SLX9 FPGA features 32 18 Kb BRAM blocks [19, p. 2], and the Cyclone V 5CSEMA5F31C6N (used in the DE1-SoC) has 397 10 Kb blocks [20, p. 22].

Figure 8.1

As shown in [Figure 8.1a](#), as the number of processor cores increases, they eventually outnumber the available BRAM blocks resulting in their memories being implemented in either distributed RAMs or ALMs, both of which can consume significant logic resources of the FPGA which reduces the maximum possible core count.

[Figure 8.1b](#) shows the FPGA resource requirements for the DE1-SoC board featuring the Cyclone V FPGA. Approximately 32 cores can be instantiated before the all the available registers and ALMs are consumed.

Reducing Memory Requirements

As shown in [Figure 8.1a](#), each core has it's own instruction read-only memory. These memories have identical contents which presents an opportunity for optimisation. In the proposed design in [Figure 8.2a](#), this memory is removed from each core and is instead available through a dedicated shared bus. This approach can be configured to be used in the Vmicro16 SoC through the `DEF_CORE_HAS_INSTR_MEM` parameter in `vmicro16_soc_config.v`, which enables the *Instruction Memory Interconnect* shown in [Figure 5.2](#).

As shown in [Figure 8.2b](#), the resource requirements using this shared memory approach is significantly less than having an instruction memory per-core. On the DE1-SoC, 64 cores can now be instantiated with a few thousand regs and ALMs left for other logic.

(a) A multi-core architecture where each core must fetch instructions externally from a global memory.

(b) DE1-SoC (Cyclone V) resource utilisation with various core counts using shared instruction memory.

Figure 8.2

Whilst this is a significant resource saving opportunity, it does have significant drawbacks. In the shared instruction memory approach, each core must now fetch its instruction from the instruction memory interconnect which is subject to the arbiter and its scheduling algorithm. The arbiter uses the same algorithm as the peripheral interconnect arbiter meaning that cores receive access incrementally, and as discussed in [Section 5.3.2](#), this results in significant delays in many-core designs. This drawback is further explained in [Section 8.3.3](#).

8.2.2 Maximum Frequency

[Figure 8.3](#) below shows the maximum clock frequency for the design (F_{max}) on the Cyclone V on the DE1-SoC. As expected, having more cores results in more logic and thus a longer propagation delays to each core. System designers should consider the number of cores in their design as having fewer, faster, cores may outperform having more, slower, cores in some use-cases.

Figure 8.3: Cyclone V maximum design frequency for various core count configurations.

8.3 Scenario Performance

To evaluate the performance of the system-on-chip, scenarios encompassing computational problems that are reflective of real-world applications are compiled and ran on the design.

8.3.1 Scenario Overview

The scenario is a software program that runs a parallel implementation of the summation function, i.e. `sum [1..10]` which returns 55. While this may seem too simple at first to measure performance of a multi-core system-on-chip, the function is actually quite appropriate as it encompasses various parallel problems, such as: a fixed time/size serial part; broadcasting of the data set (in this case the range of the summation); thread synchronisation (to know when the data is ready and to schedule gathering of intermediary results); and is highly scalable.

The summation task flow is as follows:

1. Root (core #0) broadcasts the range of the summation (i.e. sum 1 to 10) to all cores via the global shared memory.
2. Non-root cores wait for this broadcast to finish (memory barrier), then calculate their own subset of the range to sum. For example, if Root broadcasts that there are 240 samples and 10 cores in the system, each core calculates the subset size:

$$240/10 = 24 \quad (8.1)$$

calculations starting from:

$$ID_{CORE} * 24 \quad (8.2)$$

For example, Core #5 will start its 24 sample subset summation from

$$5 * 24 = 120 \quad (8.3)$$

effectively performing `sum [120..123]`.

3. All cores perform an intermediary summation over their subset of the range (serial part).
4. All cores attempt to add their intermediary result to a global sum value in global shared memory (mutex).
5. All cores halt, signalling that their work has been committed to the global shared memory and have finished the program.

This program is written in assembly in the file `sw/demos/asm/sum64.s` and can be compiled using the assembly compiler (developed for deliverable [ED4](#)) using the command below. The assembly compiler outputs the file `asm.s.hex` containing hex instruction words for use in Verilog's `$readmemh` function. This data is used for each core's instruction memory. The assembly program is also shown in [Section D.2](#).

```
python sw/asm.py sw/demos/asm/sum64.s
```

8.3.2 Performance Measurements

Behavioural simulation is used to measure the following metrics to estimate general performance of the system-on-chip:

- Total program run-time.
This is the time from when the reset signal is de-asserted to when all cores have halted. Each core has an output halt signal which the SoC can use to determine if all cores have halted using `wire all_halted = &core_halts;`.
- Time spent on the serial part.
The serial part of this scenario consists of the intermediary summation of it's subset range. As each core is performing this task, the average will be used.
- Time spent on communication.
This includes time spent on thread synchronisation, i.e. waiting for the global memory to become available and waiting on the root to finish broadcast. Again, the average time will be used.
- Time spent fetching instructions.
Instruction fetches occur during stage STAGE_IF of the pipeline. The behavioural test bench will record the number of clock cycles each core spends in this state, then calculate the average time spent fetching instructions.

These measurements are recorded using non-synthesisable Verilog code in both the test-bench and module code (`vmicro16_soc.v`).

8.3.3 Performance Results

The scenario program was simulated on system configuration with 1 to 30 cores with a 50 MHz clock. Figure 8.4 shows the time breakdown of the multi-core system-on-chip running the scenario problem with various core counts. In these measurements all cores feature a small instruction memory which is accessed in constant time (one clock), and so this fetch time is not shown in the chart.

Figure 8.4: Chart showing how the communication times (T_{bus}) and serial times (T_{sum}) changes with core count.

The chart shows the expected shape for software parallel performance – as the number of cores increase, each core's problem space is reduced resulting in faster completion of the

summation part, and an increasing amount of time is spent on thread communication. This result matches my CUDA and MPI parallelism performance analysis results conducted in 2018 [21].

It can be seen that the total run-time is fastest near 8 cores and increases at this point when using more cores. This is likely due to the small summation range per core – with 30 cores just 8 samples per core are summed, which is extremely overkill and not representative of what a 30-core plus system should be used for.

If a much larger summation range was used (effectively representing a more appropriate scenario for systems with high core counts), the chart shape would stretch horizontally, resulting in the fastest time being on a higher core count than 8.

With high-core counts (16+) it can be seen that the communication time ($T_{bus.T}$) increases significantly. This is likely due to the rotating arbiter design. As discussed in [Section 5.3.2](#), the arbiter grants bus access to the next core incrementally after the previous core finishes. For large core systems, this can result in large time penalties. For example, if core #30 is blocking all other cores and the arbiter is lagging behind granting access to core #5, it will take a significant amount of time for the arbiter to reach core #30 to unblock the system.

8.3.4 Shared Instruction Memory Impact

As previous discussed in [Section 8.2.1](#), using a shared instruction memory approach reduces the size of the design but will result in increasingly long instruction fetches as the core count increases. [Figure 8.5](#) below shows the same scenario but using shared instruction memory. The shape of the chart remains similar, however the total run-time is close to double the time of the per-core instruction memory results, and increases significantly with more cores.

Figure 8.5: Similar to [Figure 8.4](#) but using shared instruction memory to reduce block memory requirements per core.

As with [Figure 8.4](#), using too many cores for a small data set can result in the scenario taking longer than a single core.

8.4 Analysis Review

There are several takeaways from these results:

1. Use an appropriate number of cores for the dataset size.
Too few cores result in longer work times and shorter communication times, and too many cores results in shorter work times and longer communication times.
2. Use an appropriate arbitration scheme to prevent blocking the system for too long.
In this design, and likely others, the blocking core is known by the global shared memory (via the locking cells) meaning that this information can be passed to the arbiter to give priority, while still avoiding deadlocks, to the blocking core.
3. Use an appropriate number of cores and still have space for other business logic.
4. More cores may result in lower clock frequencies.
From [Figure 8.3](#), the single-core design can be ran at ≈ 95 MHz while the 4-core design only ≈ 65 MHz (a $\approx 30\%$ decrease). The parallel speed improvements from having more cores may be less than a single fast core.

System designers should experiment with their algorithm and these takeaways to determine the approximate number of processor cores for their requirements, be that algorithm time, size, clock frequency, or compilation time.

Chapter 9

Conclusion

9.1	Overview	55
9.2	Review Against Project Deliverables	55
9.2.1	Core Deliverables	55
9.2.2	Extended Deliverables	56
9.3	Future Work	57

9.1 Overview

This project's primary goal was to explore and understand the design considerations of multi-core systems designing and implementing one from scratch. A 16-bit processor core was created and connected to a scalable multi-master bus interconnect to enable communication to peripherals. More processor cores were added and software was written to implement multi-threaded communication primitives, such as mutexes and memory barriers, to enable core-to-core communication.

9.2 Review Against Project Deliverables

This section will compare against the project deliverables initially outlined in [Chapter 3 Project Overview](#).

9.2.1 Core Deliverables

This project has achieved all core deliverables. A brief overview of each accomplishment is described below.

CD1 Design a compact 16-bit RISC instruction set architecture.

Achieved. A new 16-bit instruction set has been designed and implemented, nicknamed *Vmicro16* (Verilog microprocessor 16-bits).

CD2 Design and implement a Verilog RISC core that implements the ISA in [CD1](#).

Achieved. The implementation is found in `vmicro16.v`.

CD3 Design and implement an on-chip interconnect for multi-core processing (2 to 32 cores) using the RISC core from CD2.

Achieved. The AMBA APB bus was chosen and adapted for multi-master support. While the design is simple and lacks in performance, it does not consume a significant amount of area, leaving space for more cores and peripherals.

CD4 Analyse performance of serial and parallel software algorithms, such as parallel DFT, on the processor.

Achieved. A summation computation was chosen to demonstrate effectiveness in various parallel computational problems, such as subset calculation, thread communication, and broadcast/gather procedures.

CD5 Allow the RISC core to be easily compiled to multiple FPGA vendors (Xilinx, Altera).

Achieved. The design has been successfully compiled on Quartus Prime, Xilinx Vivado, Xilinx ISE, ModelSim, and Icarus Verilog. The design has been successfully implemented on the Cyclone V and Spartan-6 FPGA devices.

9.2.2 Extended Deliverables

ED1 Design a RISC core with an instructions-per-clock (IPC) rating of at least 1.0 (a single-cycle CPU).

Not achieved. Although present in the interim update, it was decided to remove this feature due to its complexity and possibility of it hindering multi-core and interrupt integration.

ED2 Design a RISC core with a pipe-lined data path to increase the design's clock speed.

Achieved. Data in the processor's pipeline is clocked through stages of flip-flops to reduce the critical path.

ED3 Design a scalable multi-core interconnect supporting arbitrary (more than 32) RISC core instances (manycore) using Network-on-Chip (NoC) architecture.

Not achieved. The implemented design uses traditional multi-core communication techniques (shared memory communication, mutexes, etc.) rather than a NoC architecture. While the NoC design would be more scalable, it would be of much higher complexity and therefore out-of-scope for this project's timeline.

ED4 Design a compiler-backend for the PRCO304 [11] compiler to support the ISA from CD1. This will make it easier to build complex multi-core software for the processor.

Somewhat achieved. While a compiler backend was produced that allowed high-level code to be compiled and run on the Vmicro16 processor, it lacked many multi-core and interrupt features. In addition, many unforeseen bugs were found in the original compiler, and it was decided instead to build and use a simpler text-assembly based compiler, `asm.py`.

ED5 The RISC core can communicate to peripherals via a memory-mapped addresses using the Wishbone bus.

Achieved. Although not Wishbone, AMBA APB was used instead as it's interface is more intuitive.

ED6 Implement various memory-mapped peripherals such as UART, GPIO, LCD, to aid visual representation of the processor during the demonstration viva.

Somewhat achieved. Modular UART, GPIO, watchdog, bus recovery, and memory peripherals were created to visually demonstrate features of the design. An LCD peripheral was not made due to time-constraints, however it would have been beneficial to do so to demonstrate conditional compilation for different development boards. A collection of software demos utilising these modules can be found in [Appendix D](#).

ED7 Store instruction memory in SPI flash.

Not achieved.

ED8 Reprogram instruction memory at runtime from host computer.

Achieved. The global instruction memory (if enabled, see [Appendix C](#)) supported run-time programming over the UART0 interface. An example host-programmer application is provided in `sw/prog.py`.

ED9 Processor external debugger using host-processor link.

Not achieved.

9.3 Future Work

There are two types of improvements that could be performed to improve the project. The first is to perform various refinements to existing project features to produce a higher quality, more efficient and performant design. The second is to add features for the purpose of gaining knowledge.

A few of these improvements are described below:

1. Use AMBA AHB for processor-to-processor and processor-to-memory communication. This will allow for higher throughput and larger data transfers between these devices. If instructions can be fetched in bulk from the instruction memory via AHB, it would enable more processor optimisations such as out-of-order execution and branch prediction. The AMBA APB interface would still be used for communicating with the peripherals.
2. Re-add instruction pipelining to each processor.
While this was removed due to it's complexity and fears of hindering multi-core and interrupt integration, now that these features have been accomplished and understood, instruction pipelining should be added to improve instruction throughput.
3. As discussed in [Section 5.3.2](#), a more complex arbiter that features priority and inputs from the global shared memory would have resulted in significantly lower wait times and therefore performance.

Appendix A

Peripheral Information

A.1 Special Registers	60
A.2 Watchdog Timer	61
A.3 GPIO Interface	61
A.4 Timer with Interrupt	62
A.5 UART Interface	62
B.1 Register Set Multiplex	63
B.2 Instruction Set Architecture	64

To provide user's with useful functionality, common system-on-chip peripherals were created. This section describes each peripheral and it's design decisions. The full memory-map is shown in [Figure 6.5](#).

A.1 Special Registers

From the software perspective, it is important for both the developer and software algorithms to know the target system's architecture to better utilise the resources available to them. Software written for one architecture with N cores must also run on an architecture with M cores. To enable such portability, the software must query the system for information such as: number of processor cores and the current core identifier. Without this information, the developer would be required to produce software for each individual architecture (e.g. an Intel i5 with 4 cores or an Intel i7 with 8 cores, or an NVIDIA GTX 970 with 1664 CUDA cores.

The special register peripheral is shown below.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
								CORE_ID								0080	R
								NUM_CORES								0081	R
SHARED_MEMORY cells (default 4096)																0082	R
								NUM_PERIPHERALS								0083	R
SCRATCH_MEMORY cells (default 64)																0084	RW
User defined																0085	RW
⋮																	
User defined																008F	RW

Figure A.1: Vmicro16 Special Registers layout (0x0080 - 0x008F).

A.2 Watchdog Timer

In any multi-threaded system there exists the possibility for a deadlock – a state where all threads are in a waiting state – and algorithm execution is forever blocked. This can occur either by poor software programming or incorrect thread arbitration by the processor. A common method of detecting a deadlock is to make each thread signal that it is not blocked by resetting a countdown timer. If the countdown timer is not reset, it will eventually reach zero and it is assumed that all threads are blocked as none have reset the countdown.

In this system-on-chip design, software can reset the watchdog timer by writing any 16-bit value to the address 0x00B8.

This peripheral is optional and can be enabled using the configuration parameters described in [Configuration Options](#).

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reset Watchdog																00B8 W

A.3 GPIO Interface

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
								GPIO0 Output								0090 RW
GPIO1 Output																0091 RW
								GPIO2 Output								0092 RW
								GPIO3 Input								0093 R

On the DE1-SoC board, GPIO0 is assigned to the LEDs, and GPIO1 and GPIO2 to the 6 seven-segment displays.

A.4 Timer with Interrupt

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Load Value																0200 RW
													I	R	S	0201 W
Prescaler																0202 W

Clock Frequency Uses top level FPGA clock (normally 50 MHz).

Load Value Value to count down from each clock.

I Interrupt enable bit. Default 0.

R Reset Load Value and Prescaler values to their last written value.

S Start the timer countdown. 1 = start. 0 = stop.

Prescaler Number of clocks per FPGA clock to wait between each decrement.

A.5 UART Interface

15	8	7	1	0			
					Transmit Data	00A0 W	
					Receive Data	00A1 R	
					E	I	00A2 RW

E Enable the UART component.

I Enable an interrupt upon receiving new data. Default 1.

Note: If DEF_USE_REPROG is enabled in vmicro16_soc_config.v then the Receive Data register will be reserved for programming the instruction memory, resulting in reads and writes to addresses 0x00A1 and 0x00A2 to return 0.

Appendix C

Configuration Options

C.1 System-on-Chip Configuration Options	65
C.2 Core Options	66
C.3 Peripheral Options	67

The following configuration options are defined in `vmicro16_soc_config.v`.

Defaults with empty/blank values signifies that the preprocessor define is commented out/not defined/disabled by default/computed by other parameters.

C.1 System-on-Chip Configuration Options

Macro	Default	Purpose
CORES	4	Number of CPU cores in the SoC
SLAVES	9	Number of peripherals
DEF_USE_WATCHDOG	//	Enable watchdog module to recover from deadlocks and infinite loops. Requires DEF_GLOBAL_RESET.
DEF_GLOBAL_RESET	//	Enable synchronous reset logic. Will consume more LUT resources. Does not reset BRAM blocks.
DEF_USE_BUS_RESET	//	Detect bus stalls or errors to soft-reset the whole design. Requires DEF_USE_WATCHDOG.

Table C.1: SoC Configuration Options

C.2 Core Options

Macro	Default	Purpose
DATA_WIDTH	16	Width of CPU registers in bits
DEF_CORE_HAS_INSTR_MEM	//	Enable a per core instruction memory cache
DEF_MEM_INSTR_DEPTH	64	Instruction memory cache per core
DEF_MEM_SCRATCH_DEPTH	64	RW RAM per core
DEF_ALU_HW_MULT	1	Enable/disable HW multiply (1 clock)
FIX_T3	//	Enable a T3 state for the APB transaction
DEF_USE_REPROG	//	Programme instruction memory via UART0. Requires DEF_GLOBAL_RESET. Enabling this will reserve the UART0 RX port for exclusive use for programming the instruction memory. Software reads of UART0 RX will return 0.

Table C.2: Core Options

C.3 Peripheral Options

Macro	Default	Purpose
APB.WIDTH		AMBA APB PADDR signal width
APB.PSELX_GPIO0	0	GPIO0 index
APB.PSELX_UART0	1	UART0 index
APB.PSELX_REGS0	2	REGS0 index
APB.PSELX_BRAM0	3	BRAM0 index
APB.PSELX_GPIO1	4	GPIO1 index
APB.PSELX_GPIO2	5	GPIO2 index
APB.PSELX_TIMR0	6	TIMR0 index
APB.BRAM0_CELLS	4096	Shared memory words
DEF_MMU_TIM0_S	16'h0000	Per core scratch memory start/end address
DEF_MMU_TIM0_E	16'h007F	"
DEF_MMU_SREG_S	16'h0080	Per core special registers start/end address
DEF_MMU_SREG_E	16'h008F	"
DEF_MMU_GPIO0_S	16'h0090	Shared GPIO0 start/end address
DEF_MMU_GPIO0_E	16'h0090	"
DEF_MMU_GPIO1_S	16'h0091	"
DEF_MMU_GPIO1_E	16'h0091	"
DEF_MMU_GPIO2_S	16'h0092	"
DEF_MMU_GPIO2_E	16'h0092	"
DEF_MMU_UART0_S	16'h00A0	Shared UART start/end address
DEF_MMU_UART0_E	16'h00A1	"
DEF_MMU_REGS0_S	16'h00B0	Shared registers start/end address
DEF_MMU_REGS0_E	16'h00B7	"
DEF_MMU_BRAM0_S	16'h1000	Shared memory with global monitor start/end address
DEF_MMU_BRAM0_E	16'h1FFF	"
DEF_MMU_TIMR0_S	16'h0200	Shared timer peripheral start/end address
DEF_MMU_TIMR0_E	16'h0202	"

Viva Demonstration Examples

D.1 2-core Timer Interrupt and ISR	68
D.2 1-160 Core Parallel Summation	70

D.1 2-core Timer Interrupt and ISR

This example demo, shown during the viva, blinks an LED every 0.5 seconds via a timer interrupt. Core 0 sets up the interrupt vector (by writing the isr0 function address to the interrupt vector) and enables all interrupt sources. Core 1 sets up the timer interval peripheral to produce an interrupt every 0.5 seconds. Core 1 also performs the interrupt handler (isr0): toggle an LED, write the state to UART0, and resets the watchdog.

```
1 // interrupts.s
2 // Toggle LED in ISR
3
4 entry:
5 // get core idx 0x80 in r7
6 movi r7, #0x80
7 lw r7, r7
8
9 // core1 sets up the timer
10 // Core0 enables interrupts and performs the isr
11 cmp r7, r0
12 movi r0, timer
13 br r0, BR_NE
14
15 // Set interrupt vector (0)
16 movi r0, isr0
17 movi r1, #0x1
18 movi r2, #0x08

89     movi    r0, #0xb8
90     sw      r1, r0
91
92     // return from interrupt
93     intr    r0, r0

```

D.2 1-160 Core Parallel Summation

This example demo performs a parallel summation of numbers 1 to 320. The algorithm *assigns* each core a subset of the summation space. It does this using the core's ID and the number of cores in the system. The following formulas determine where the subset begins and ends for each core. Core 0 broadcasts the number to sum to then each core calculates its subset start and end positions. Each core then performs a summation over it's subset then adds the result to a global shared value. After pushes it's results, the global shared value will contain the final summation result.

$$N_{samples} = 320 \quad (D.1)$$

$$N_{threads} = 64 \quad (D.2)$$

$$subset = N_{samples} / N_{threads} \quad (D.3)$$

$$start = ID * subset \quad (D.4)$$

$$end = start + subset \quad (D.5)$$

```

E.3 Assembly Compiler Listing

The following python3 program is a text assembly to hex compiler for the Vmicro16's instruction. Users can include the compiled hex-stream in their SoC design by using \$readmemh on the file into the instruction memories (mem_instr or instr_rom_apb (shared)).

All assembly programs shown in this report can be compiled by this compiler.

Usage: python3 asm.py <filename.s>

Outputs: asm.s.hex file in the PWD.

```

1  import sys
2  import math
3
4  import argparse
5
6  parser = argparse.ArgumentParser(description='Parse assembly into vmicro16 instruction words.')
7  parser.add_argument('fname', metavar='fname', type=str, help="Filename containing assembly text")
8  args = parser.parse_args()
9  print(args.fname)
10

```

E.4 Text Compiler Listing

A text-based programming language compiler was also used to write high-level software code for the Vmicro16 processor. The PRCO304 [11] compiler was extended to support the Vmicro16 instruction set architecture and some extra language features (arrays, inline assembly, pointer writing, etc.). However, the compiler ended up not being used.

The code changes to extend the compiler are available as a .patch for users to patch the compiler themselves. The patch is available from: <https://github.com/bendl/vmicro16/tree/master/sw/patch>.

Code files are found in `sw/demos/prco/*.prco`.
